“Ecology as a science is based on the negation of all things natural. It makes nature into a constituent element of an interrelationship with urban production. This marks the end of nature as an indeterminate field on its own. Now it has to be translated in terms of resources and their exploitation, and ecology…”

Frederic Migayrou

Therefore...the greatest ongoing challenge to planning is design within human-dominated ecosystems.

Key functions of trees in city making:

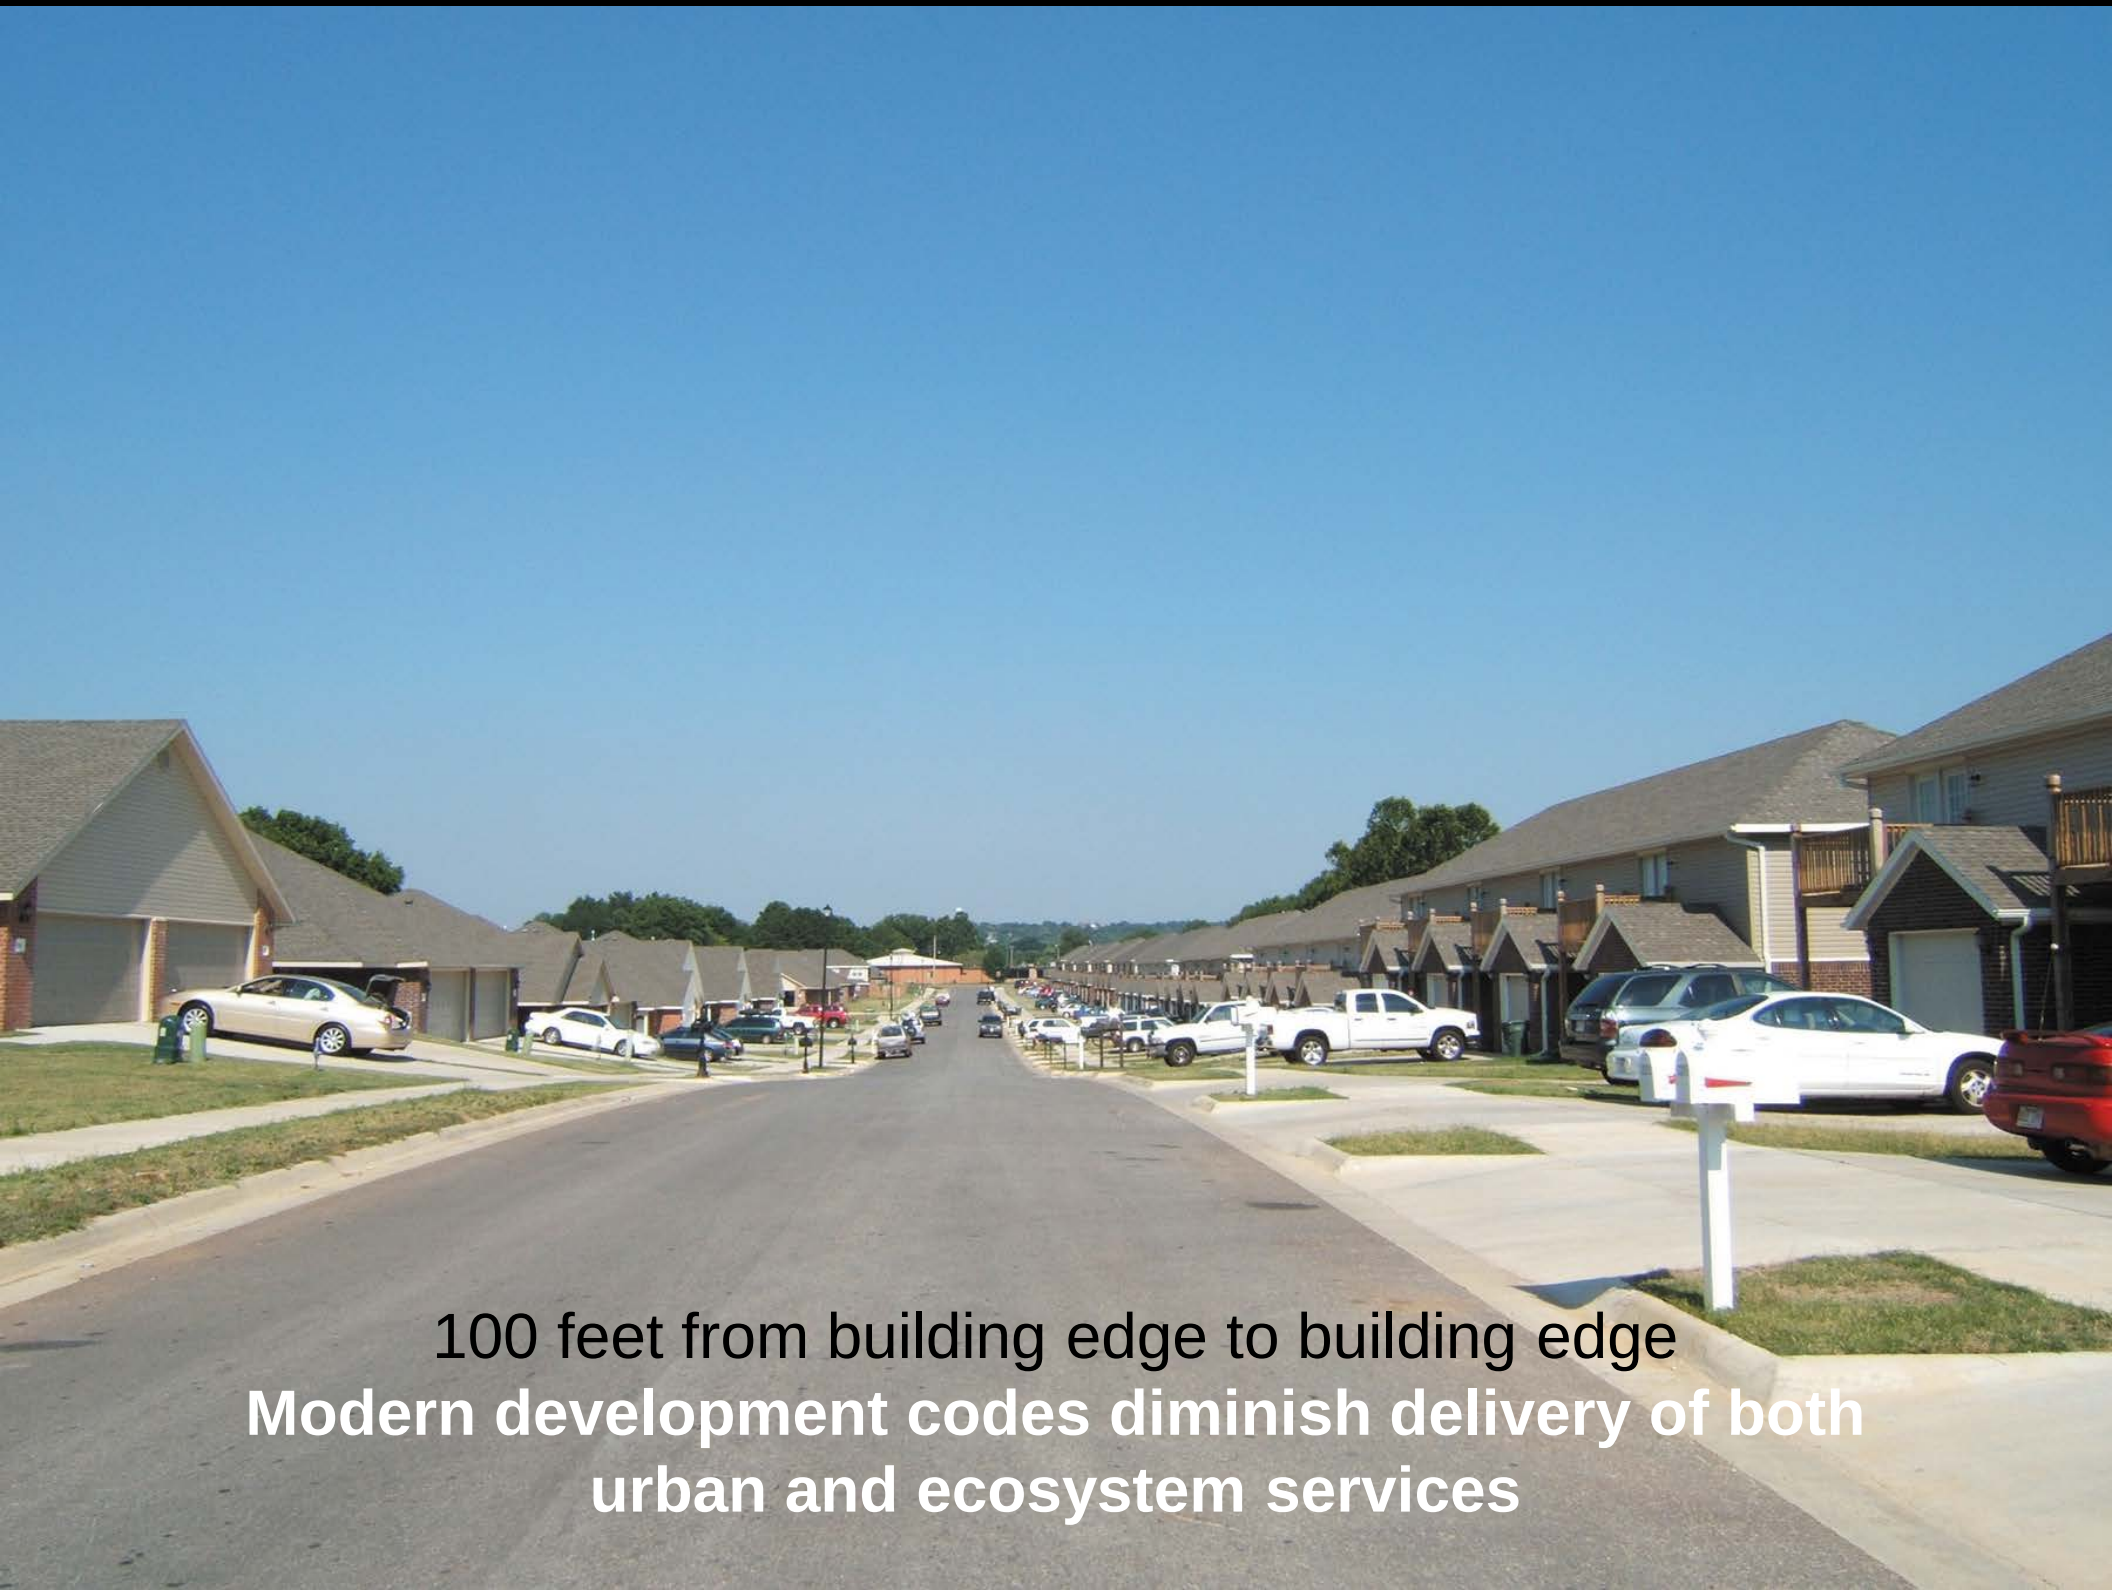
- Complete Streets
- low impact development
- edible civic landscapes

Complete Streets

- Tree longevity
- Non-traffic social functions
- Urban livability

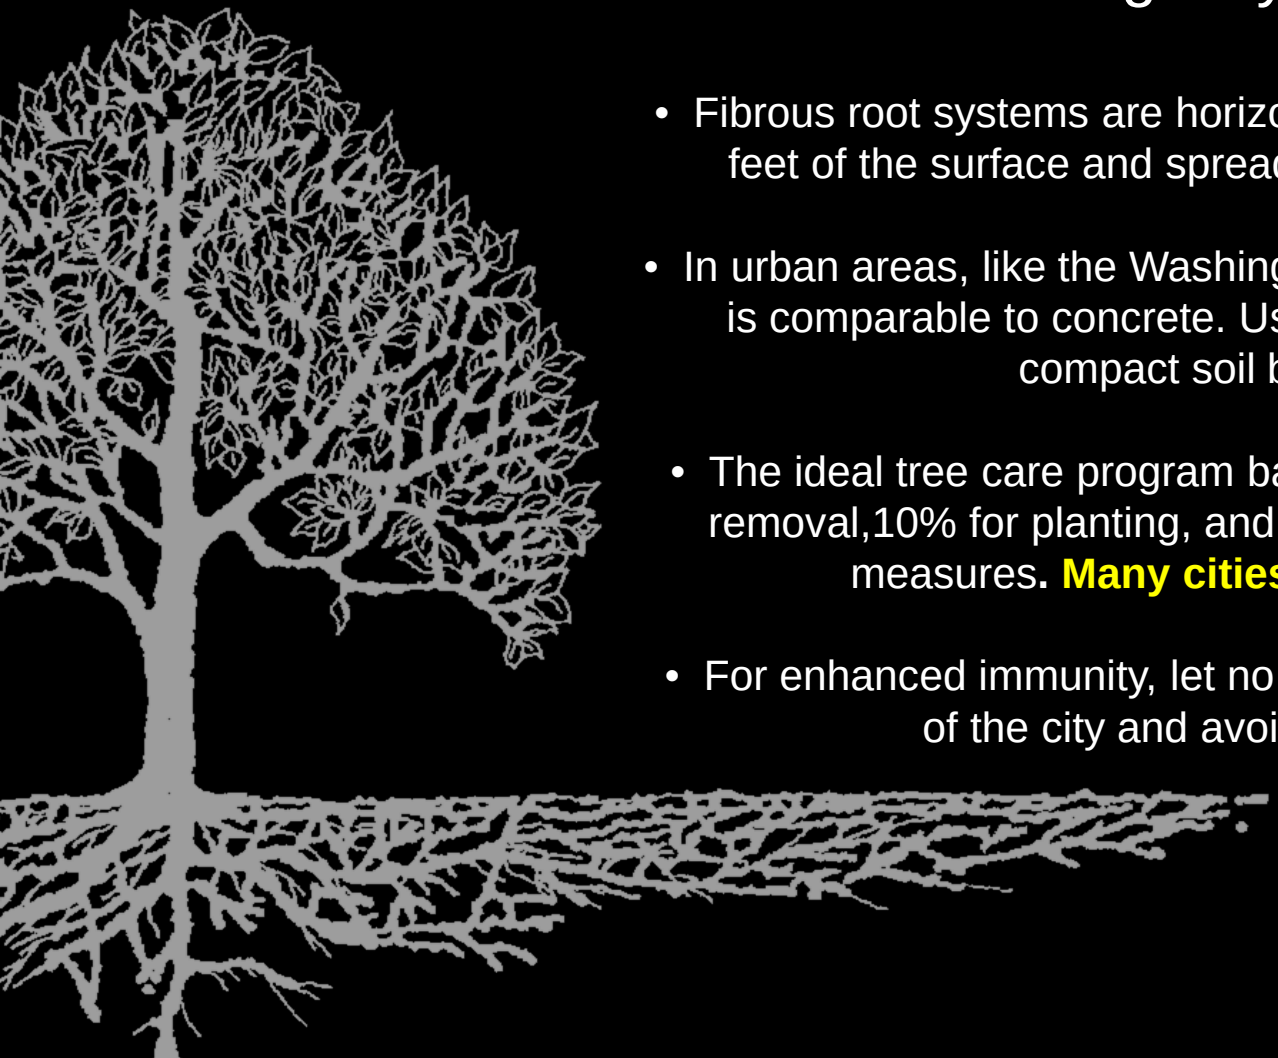
150 feet from building edge to building edge

The average life span of a contemporary urban tree is 13 years.



100 feet from building edge to building edge

Modern development codes diminish delivery of both urban and ecosystem services



For longevity, consider that:

- Fibrous root systems are horizontal as 90% of roots are within three feet of the surface and spread 2-4 times the height of the tree.

- In urban areas, like the Washington DC Mall for instance, soil density is comparable to concrete. Use geotextile cloth to limit need to compact soil beneath sidewalk.

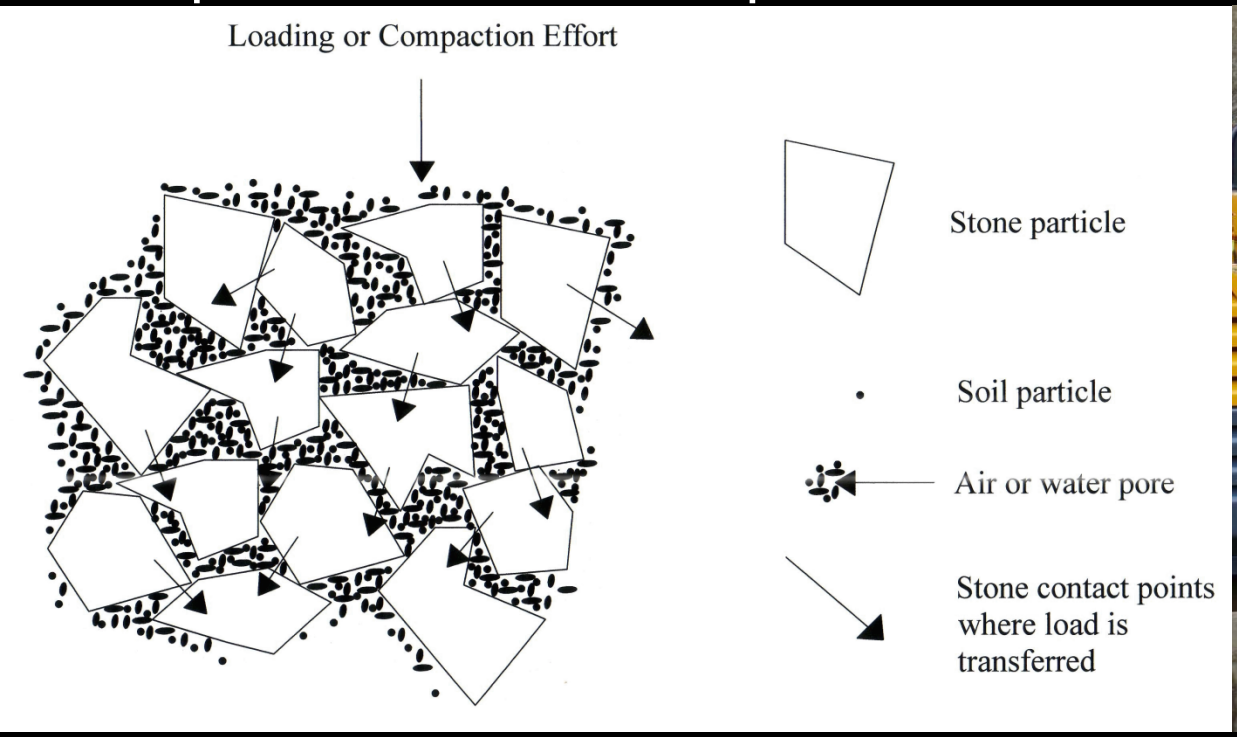
- The ideal tree care program balance is: 40% for trimming, 14% for removal,10% for planting, and remainder for other maintenance measures**. Many cities spend 80% on removal.**

- For enhanced immunity, let no one species occupy more than 10% of the city and avoid monolithic tree rows.

In Portland, trees and stormwater management have priority as constituent elements in the city's development regulations.

While street trees were always important to Portland, the old model lacked best installation practices to sustain their longevity.

the problem of soil compaction and lack of soil oxygen and nutrients



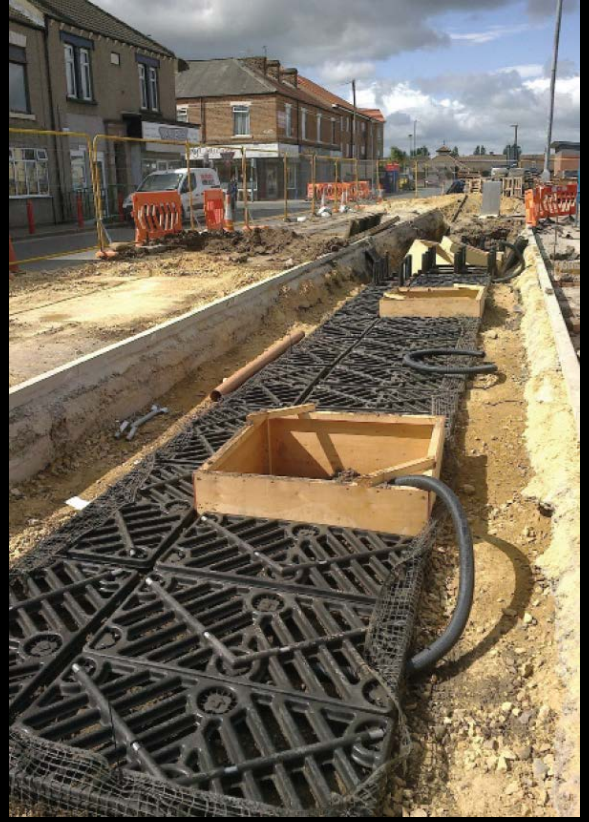
Structural Soil—CU Specification

Provide minimum 40% porosity beneath hard surfaces with light or stationary loading.

Structural Cells

For applications beneath hard surfaces with heavy and moving traffic.

premier-meats.
" A Different Class



Since rail transit requires walkable neighborhoods, transit malls incorporate trees.

Main streets, which typically lacked landscaping to maximize shopping productivity, have been retrofitted as Complete Streets with trees in their revitalization.

16th Street Mall: Denver

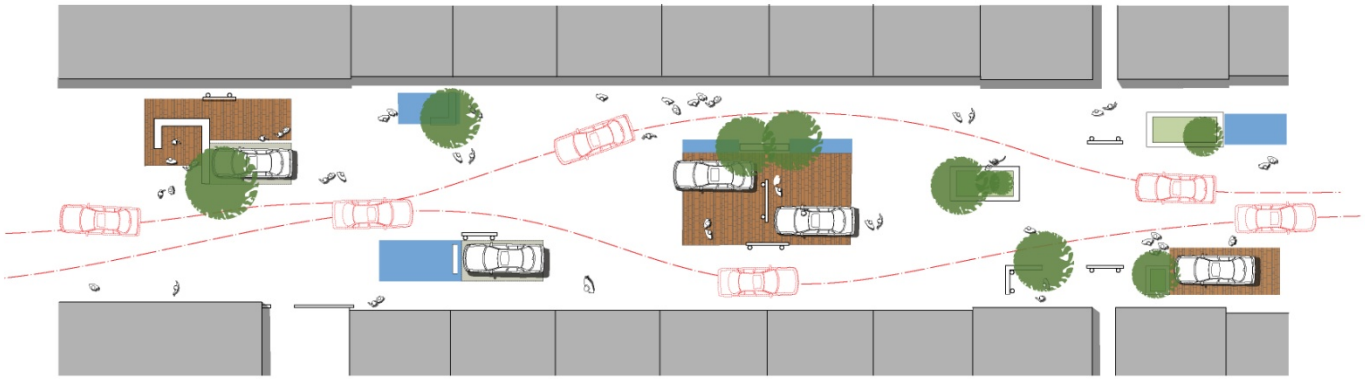
Trees set the stage for social life in streets, so that streets, once again, may deliver non-traffic services.

Strategic use of street trees to define private, semi-private, and public territories in dense, urban contexts. Green streets are essential to urban neighborhood reinvestment.

The Dutch shared street is designed first as a series of pedestrian gardens, privileging the social dimension of the street over trafficking.

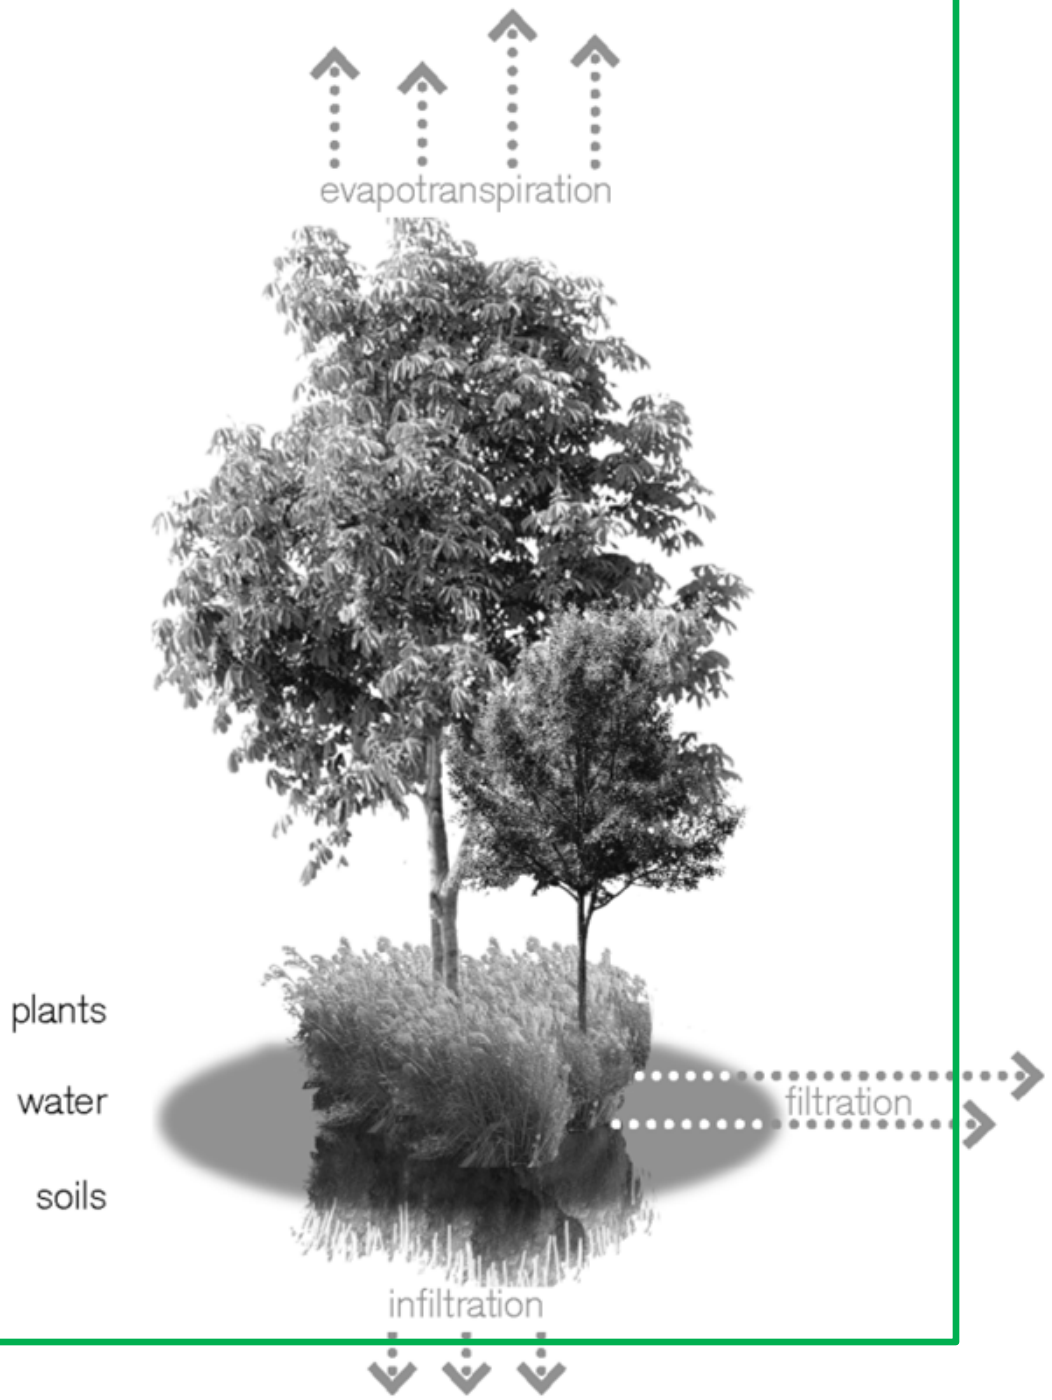
GREEN AND SHARED STREET DESIGN

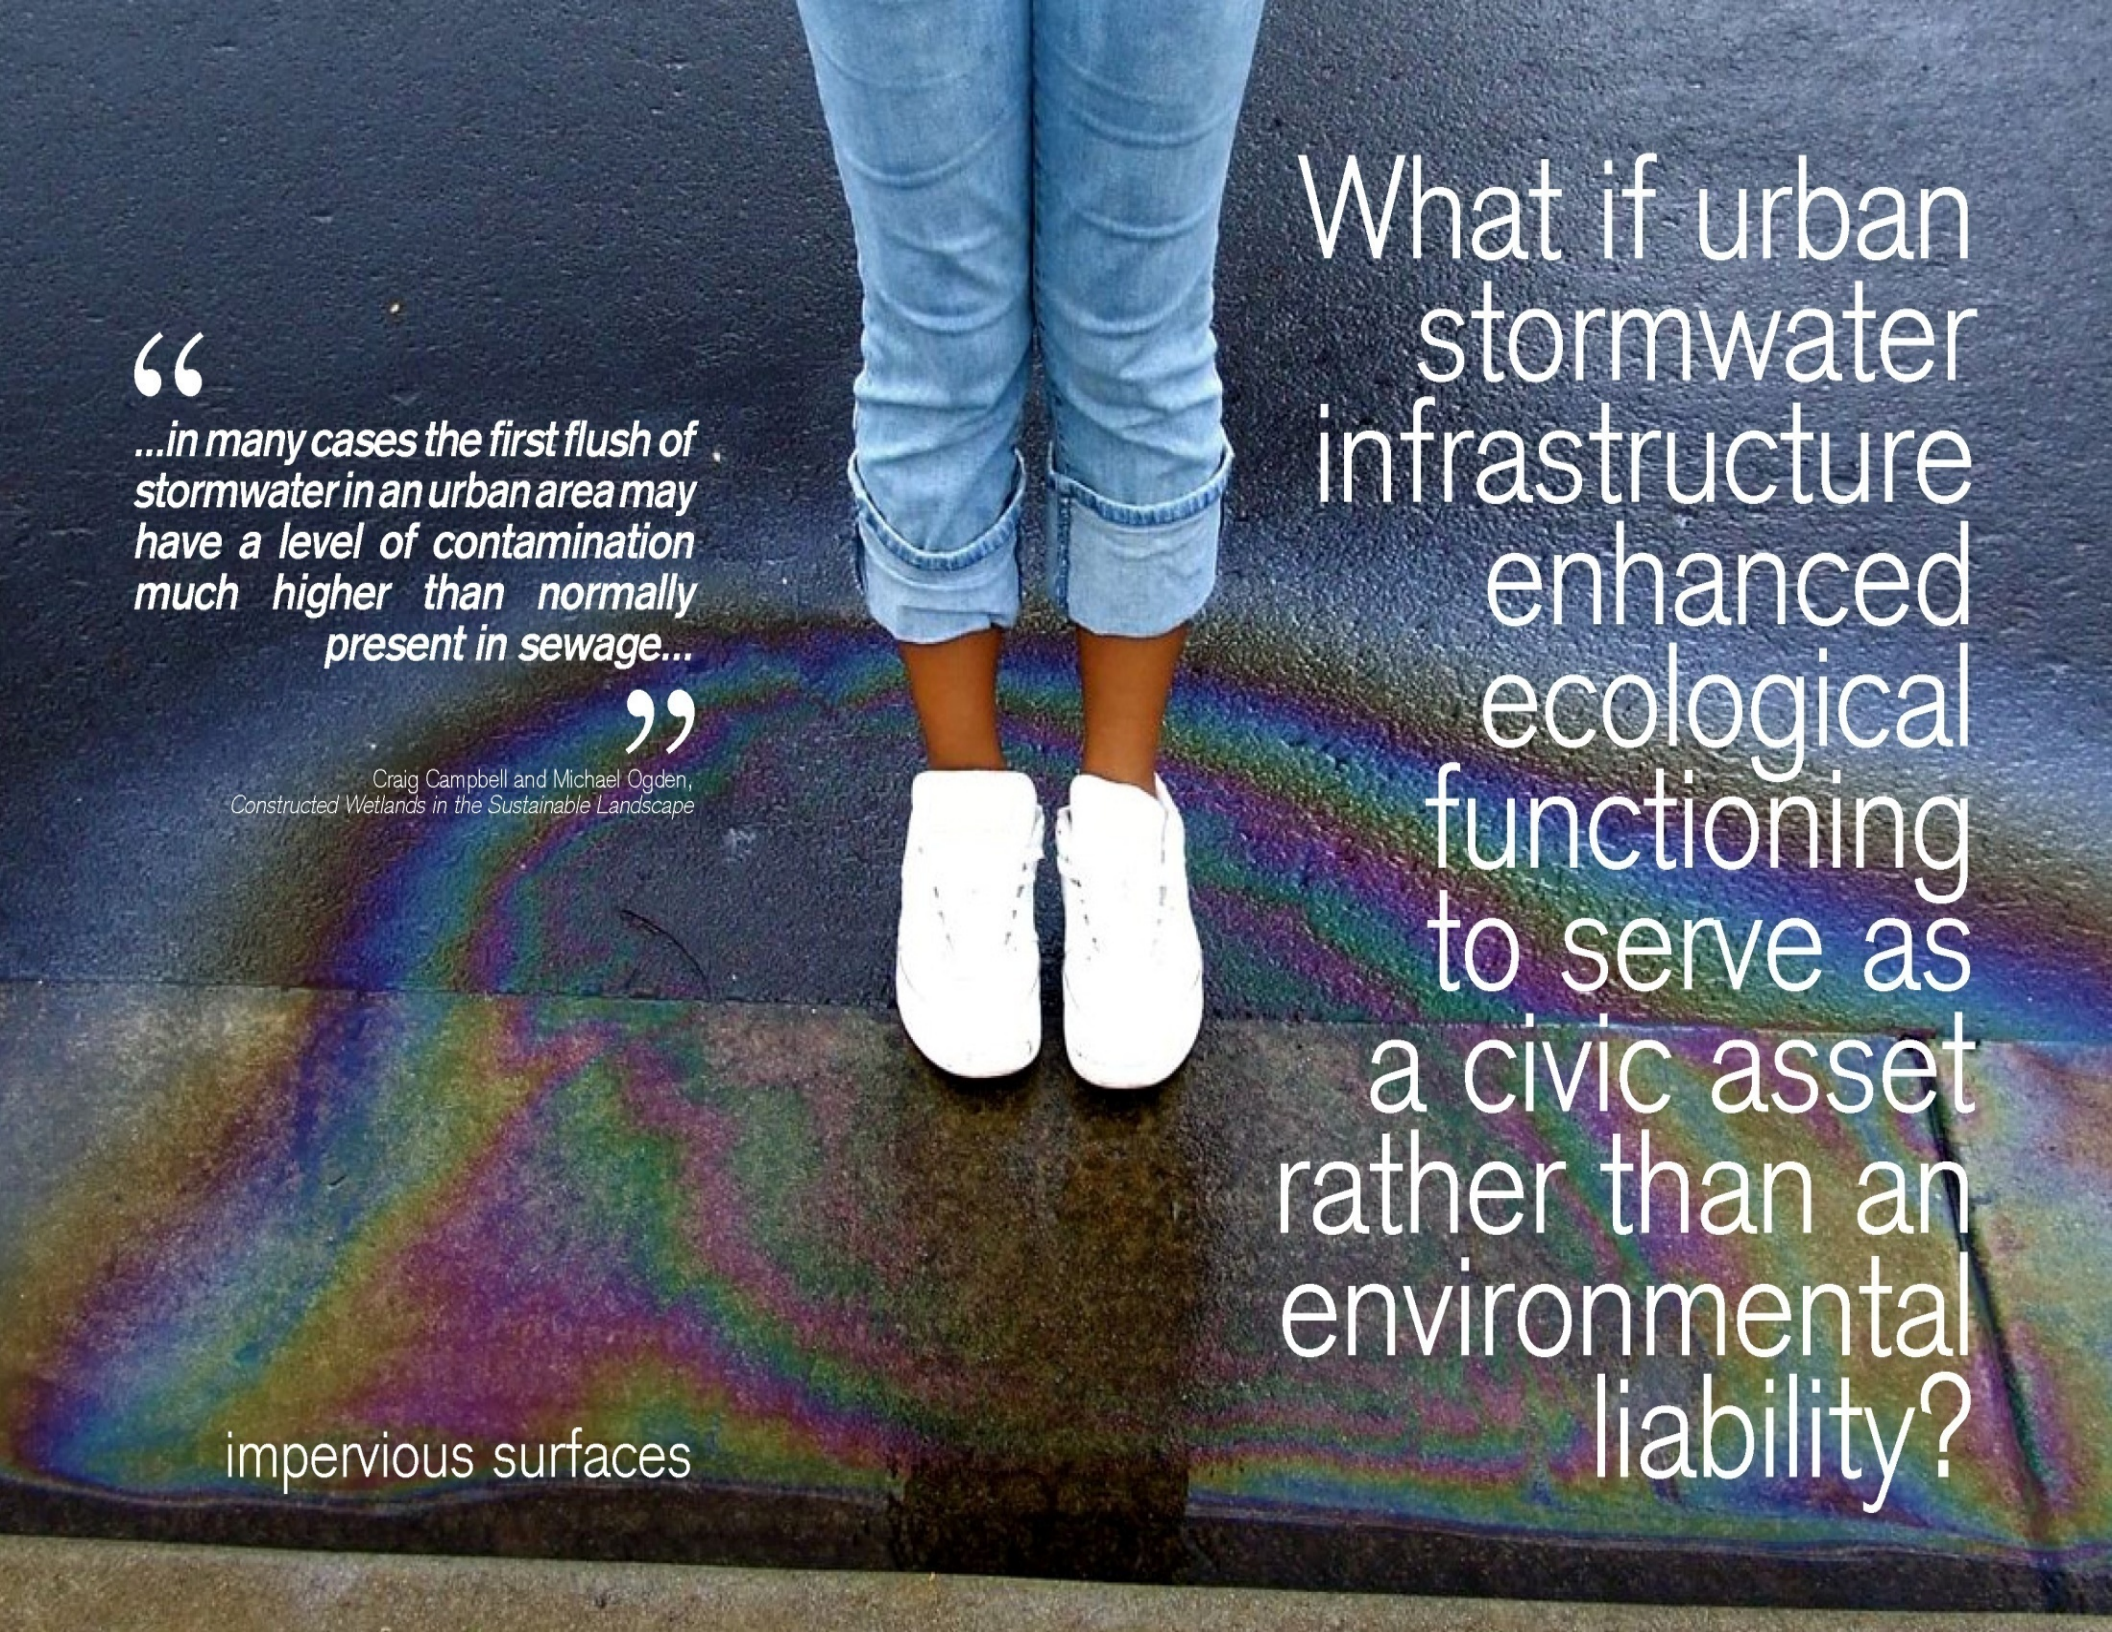
Green streets and shared streets are streets designed as gardens that balance the needs of pedestrians, transit, and stormwater management.



Low Impact Development

- Ecological services
  - Parks, not pipes!
  - Phytoremediation





“...in many cases the first flush of stormwater in an urban area may have a level of contamination much higher than normally present in sewage...”

Craig Campbell and Michael Ogden,
Constructed Wetlands in the Sustainable Landscape

impervious surfaces

What if urban stormwater infrastructure enhanced ecological functioning to serve as a civic asset rather than an environmental liability?

“Research indicates that when impervious area in a watershed reaches 10 percent, stream ecosystems begin to show evidence of degradation, and coverage more than 30 percent is associated with severe, practically irreversible degradation.”
Metro Portland, *Green Streets: Innovative Solutions for Stormwater and Stream Crossings*
urban sprawl

Lawns use more equipment, labor, fuel, and agricultural toxins than industrial farming, making lawns the largest agricultural sector in the United States.

treatment

slow → spread → soak

flow control: devices used to regulate concentrated water loads, attenuating energy flow and volume.

detention: facilities designed to intercept a volume of stormwater runoff and temporarily hold the water for gradual release, within a 24 hour period.

retention: facilities that retain a permanent pool of water, allowing for minor water quality improvement through the settling out of sediment.

filtration: processes that remove solids from stormwater through a porous media, such as sand, vegetation, or a man-made filter.

infiltration: processes in which surface water moves through soil, recharging groundwater and aquifers.

treatment: processes that metabolize pollutants from stormwater runoff.

tree box
filter

Tree Box Filter

A tree box filter or well consists of a container filled with amended soil and planted with a tree, underlain by crushed gravel media.

Tree root systems treat and uptake stormwater runoff captured from the street into the box filter. An underdrain carries treated runoff to either a surface discharge location or a larger retention system for secondary treatment. The life of the tree is short as trees will need to be replaced every five to ten years. The unit can also be planted with hardy shrubs and herbaceous plants tolerant of inundations.

Tree box filters and wells can be incorporated into urban retrofits with the added benefits of water quality improvement and reduction of the urban heat island effect. As with other filtration devices, tree box filters require occasional inspection to remove large debris and/or trash.

19

bioswale

Bioswale

A bioswale is an open, gently sloped, vegetated channel designed for treatment and conveyance of stormwater runoff.

Bioswales are a type of bioretention device in which the primary pollutant removal mechanisms are filtration by grass blades and other facultative vegetation that enhance sedimentation through adhesion of pollutants to the grass and thatch. Bioswales combine treatment and conveyance functions, reducing development costs by eliminating the need for separate conveyance systems. Their main function is to treat stormwater runoff, while the main function of rain gardens is to infiltrate runoff. Bioswales are usually located along roads, drives, or parking lots where the contributing acreage is less than five acres.

Bioswales require curb cuts, gutters or other devices that direct flow to them. They may require an underdrain where soil permeability is limited, as well as an overflow grate for larger storm events.

constructed wetland

Constructed Wetland

Constructed wetlands have a permanent pool of water designed to treat polluted stormwater through microbial breakdown of pollutants, phytoremediation, retention, settling, and adsorption (surface assimilation).

Considered to be a comprehensive treatment system, constructed wetlands can be re-established in historically drained wetland areas or low areas of a site. Plants and wetland geometry reduce stormwater velocity, allowing sediment to settle out. As with other infiltration systems, pre-treatment systems upstream help to remove sediment that may clog a wetland system, resulting in eutrophication or an oxygen deprived system.

Constructed wetlands are land rich facilities and differ from retention ponds in their shallower depths and greater vegetation coverage. They require relatively large contributing drainage areas to maintain a shallow permanent pool. Minimum contributing watershed runoff area should be at least 10 acres, although pocket wetlands may be appropriate for smaller sites if sufficient water flow is available.

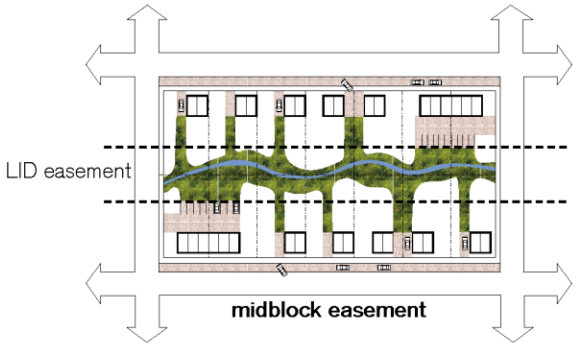
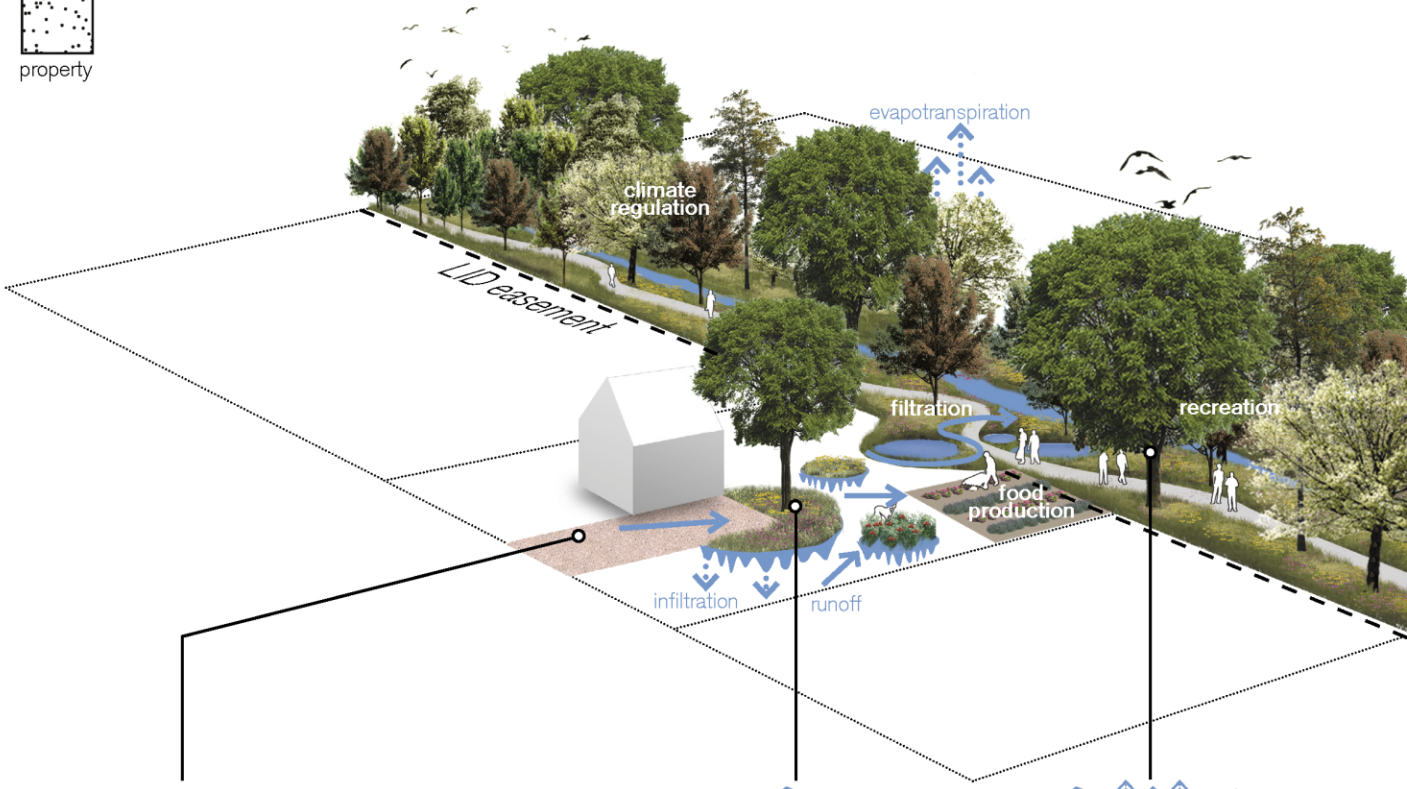
Boulevards

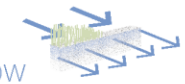
Block Design

property

Incorporate shared conservation areas into LID neighborhood fabrics by connecting property to easements.

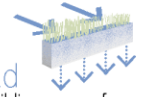






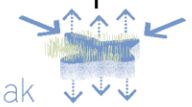
Slow

Filter stormwater through the use of pervious paving on driveways. *Pervious Paving* pp. 172-173



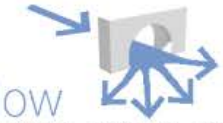
Spread

Locate buildings away from critical areas and create a series of rain gardens for attenuation and filtration of stormwater runoff from **one to ten-year storm events**. *Rain Garden* pp. 178-179



Soak

Plant and maintain vegetation in the riparian corridor. This is especially important in upstream developments. *Riparian Buffer* pp. 180-181

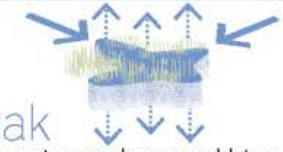


Slow

Use flush curbs to allow water to be distributed evenly over treatment facilities. *Flow Control Devices* pp. 148-149

Spread

Reduce impervious surfaces to filter and attenuate stormwater from the street. *Pervious Paving* pp. 172-173

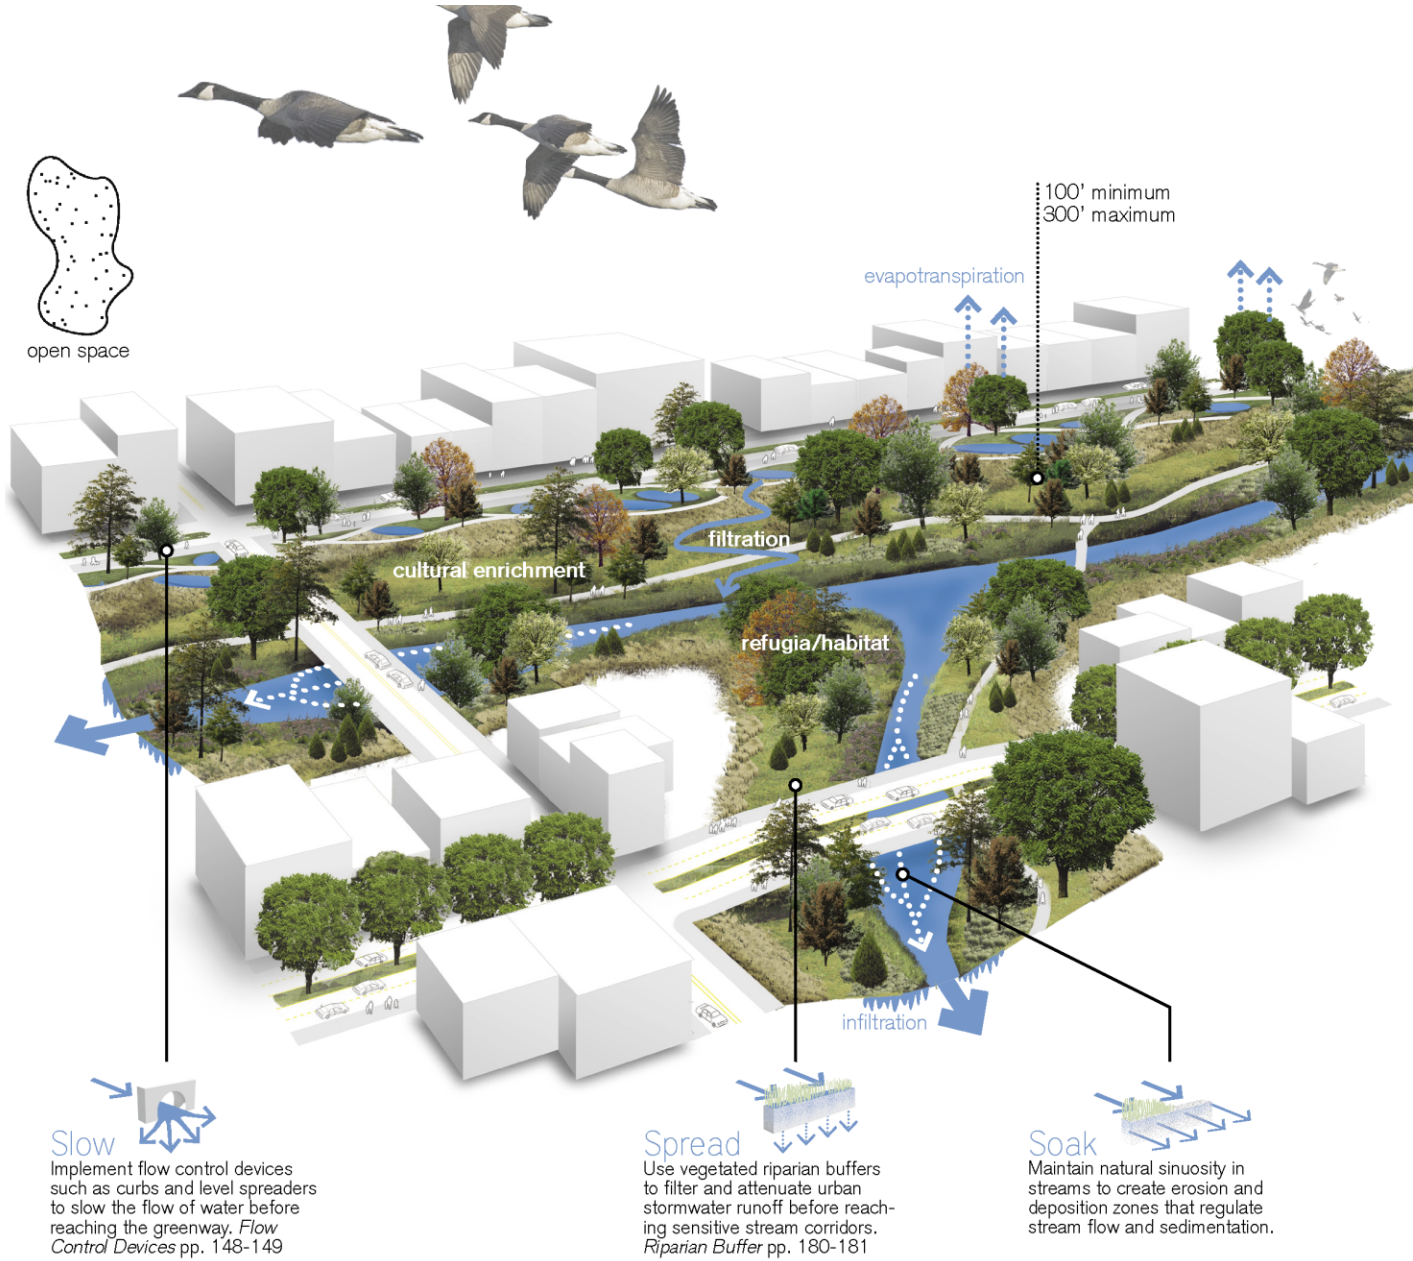


Soak

Apply rain gardens and bioswales in the easement for treatment during **one to ten-year storm events**. These facilities must be connected to secondary facilities to handle 10 to 50-year storm events. *Bioswale* pp. 182-183

Greenways

Connect open spaces to create an urban greenway that maintains nutrient, natural resource, and habitat flows through the city.



Slow

Implement flow control devices such as curbs and level spreaders to slow the flow of water before reaching the greenway. *Flow Control Devices* pp. 148-149

Spread

Use vegetated riparian buffers to filter and attenuate urban stormwater runoff before reaching sensitive stream corridors. *Riparian Buffer* pp. 180-181

Soak

Maintain natural sinuosity in streams to create erosion and deposition zones that regulate stream flow and sedimentation.

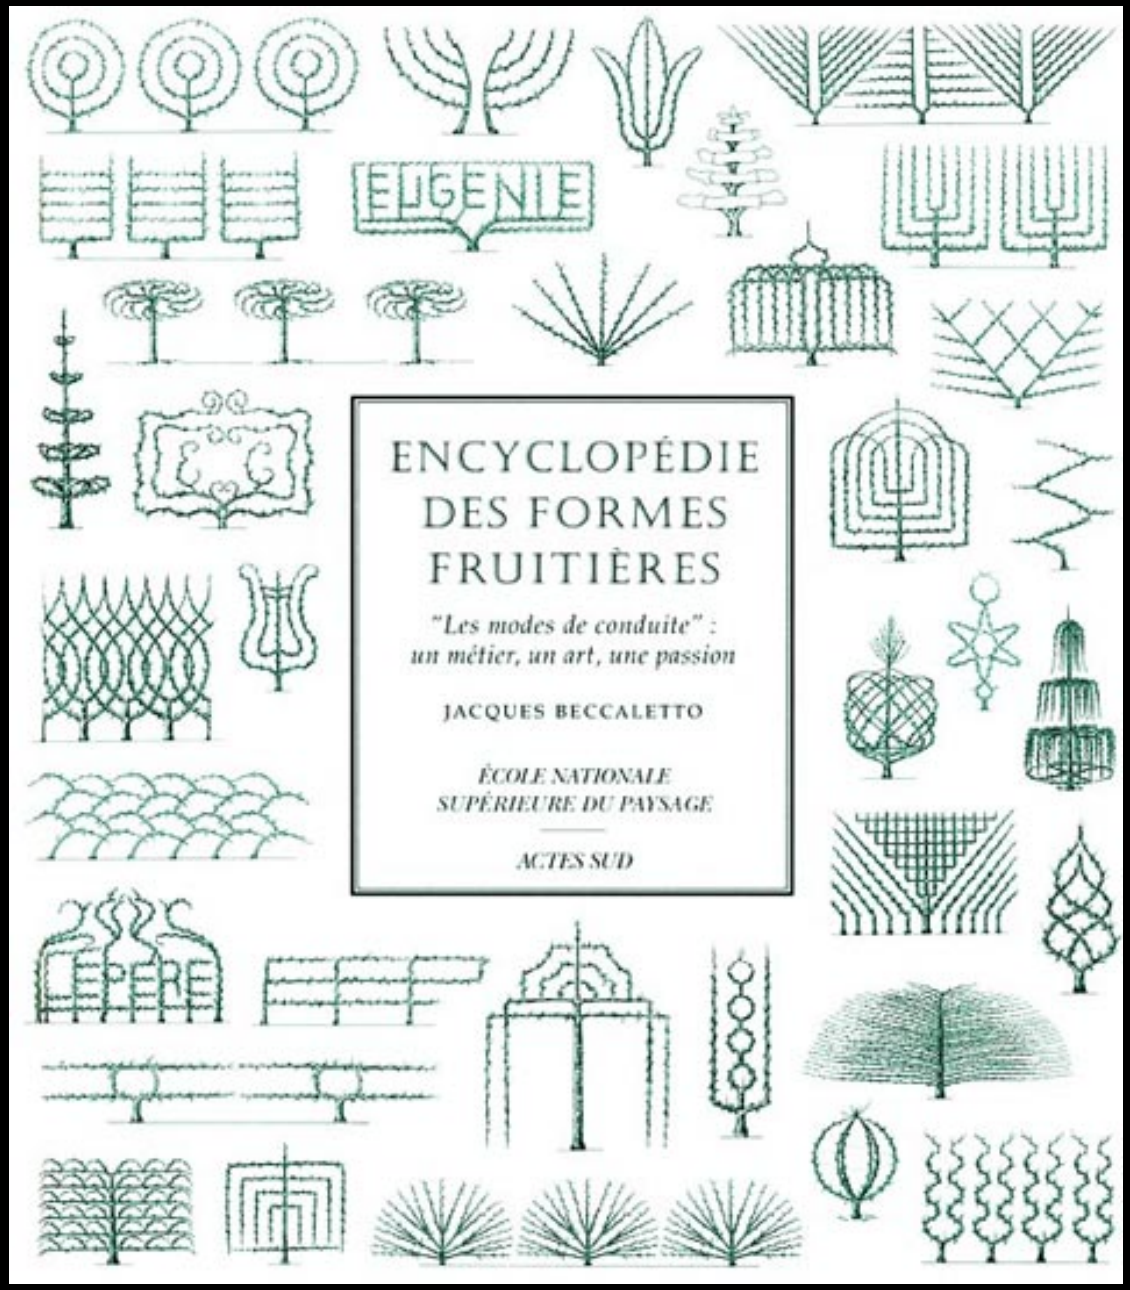
When urban landscapes were shaped for commodity production.



Espalier

Practice of controlling woody plant growth for the production of fruit by pruning and tying branches to a frame so that they grow into a flat plane.

Cordon

The most widely used form of espalier. This technique has the highest yield per unit area of space.

Pollarding

Pruning of upper branches to promote dense foliage head and to maintain predetermined height. Once used to produce new growth for harvesting of wood.

Pleaching

Technique of interweaving branches to create a hedge for stock control, and in modern times to protect fruit against frost.

Topiary

Training of evergreen, mostly woody, plants by clipping foliage and twigs to define shapes for ornamental purposes.
